# Introduction

Vehicle models depending on their dynamics can be classified into three major categories that we will develop below:

- **Dynamic Models**
- **Kinematic Models**
- **Point – Mass Models**

# Introduction

- ***Dynamic Models***

These models essentially describe the relationship that the vehicle has with the road. The complexity of these models results from the non-linearity of the relationships between the tires and the other parts of the vehicle.

# Introduction

- ***Kinematic Models***

These models consist a structure of equations that describe the geometry of the vehicle, representing the behavior of the vehicle in motion and during maneuvers.

# Introduction

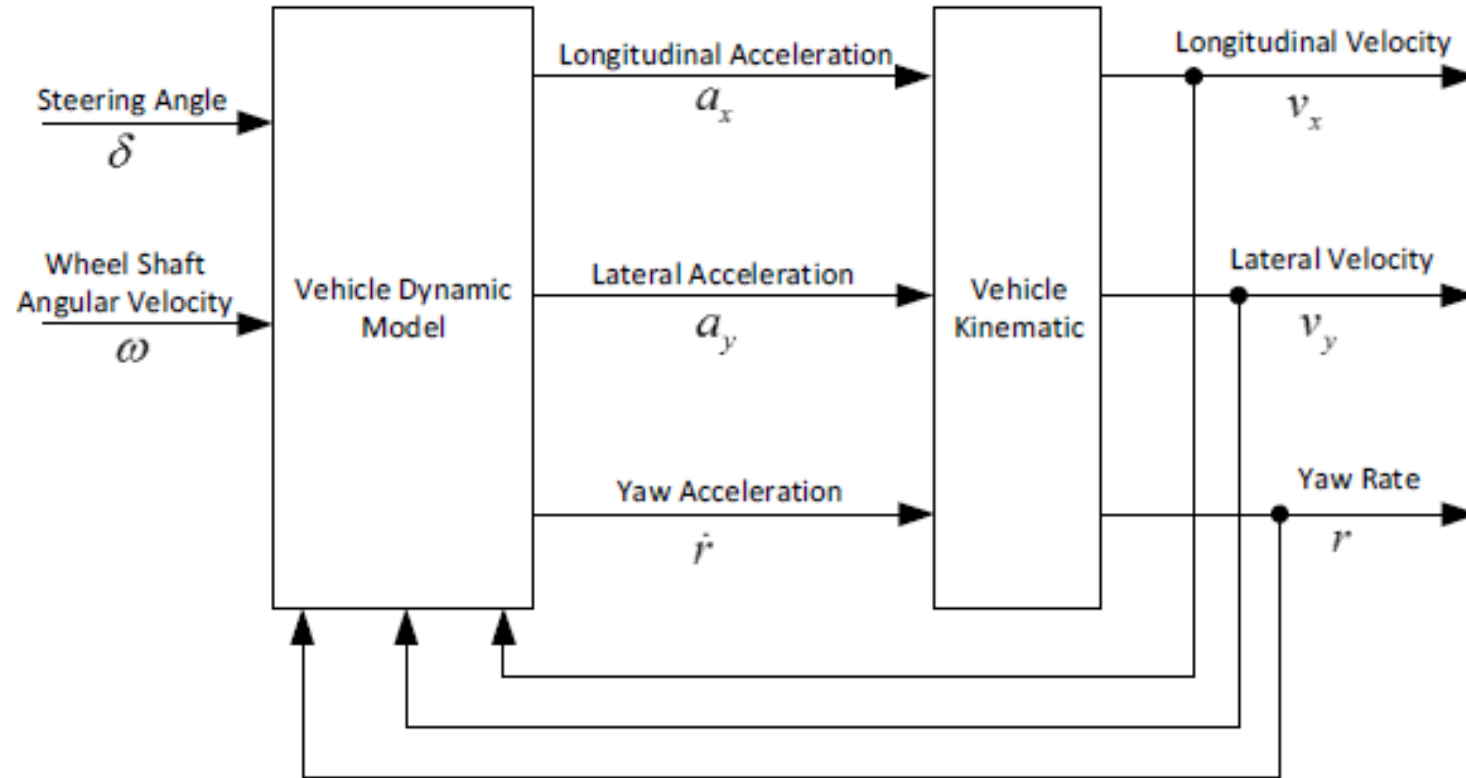

Figure 1: Diagram of Dynamic and Kinematic Model for Autonomous Driving [TM15].

# Dynamic Models

To describe the car dynamics will be used three different frames:

- **Inertial Frame:** it is described as  $(\mathbf{e}_X, \mathbf{e}_Y, \mathbf{e}_Z)$
- **Vehicle Frame:** it is described as  $(\mathbf{e}_x, \mathbf{e}_y, \mathbf{e}_z)$
- **Pneumatic or Tire Frame:** it is described as  $(\mathbf{p}_{xi}, \mathbf{p}_{yi}, \mathbf{p}_{zi})$  where the  $i$  is associated with the wheel of the vehicle  $i = 1, \dots, 4$

# Dynamic Models

Figure 2: The Vehicle – Tire frame of a four wheel car.

# Car – Body Dynamics

- The slow dynamics, include six different variables, namely the **longitudinal**  $V_x$ , **lateral**  $V_y$  and **vertical**  $V_z$  velocities and the **roll**  $\dot{\theta}$ , **pitch**  $\dot{\phi}$  and **yaw**  $\dot{\psi}$  angular velocities.
- The model inputs are the longitudinal and lateral forces  $F_{xi}$  and  $F_{yi}$  applied by the road on the different wheels  $i$  in the vehicle frame (or equivalently  $F_{xpi}$  and  $F_{ypi}$  in the pneumatic frame). This concept shown in Figure 3.

# Car – Body Dynamics

In the following Figure we see the Dynamics of a car which moves in a hill. We must describe the  $F_{aero}$ , which consist the air force that hits the car.

Figure 4: Applied Forces in a car [POL18].

# Car – Body Dynamics

Here we will describe the four-wheel vehicle model dynamics. Compared to the dynamic bicycle model, the slope and road-bank angle are defined, as well as the roll, pitch and vertical motions.

Figure 5: Four - Wheel Dynamic Model [POL18].

# Car – Body Dynamics

The suspension force variation  $F_{s1}$  applied at wheel  $i$  depends on the variation of the length of the suspension  $\Delta z_{s1} = z_{si} - z_{ti}$ .

The normal reaction  $F_{zi}$  force applied by the road on wheel  $i$  is given by the following Equations. The  $P_r$  is the weight of the wheel as shown in Figure 6.

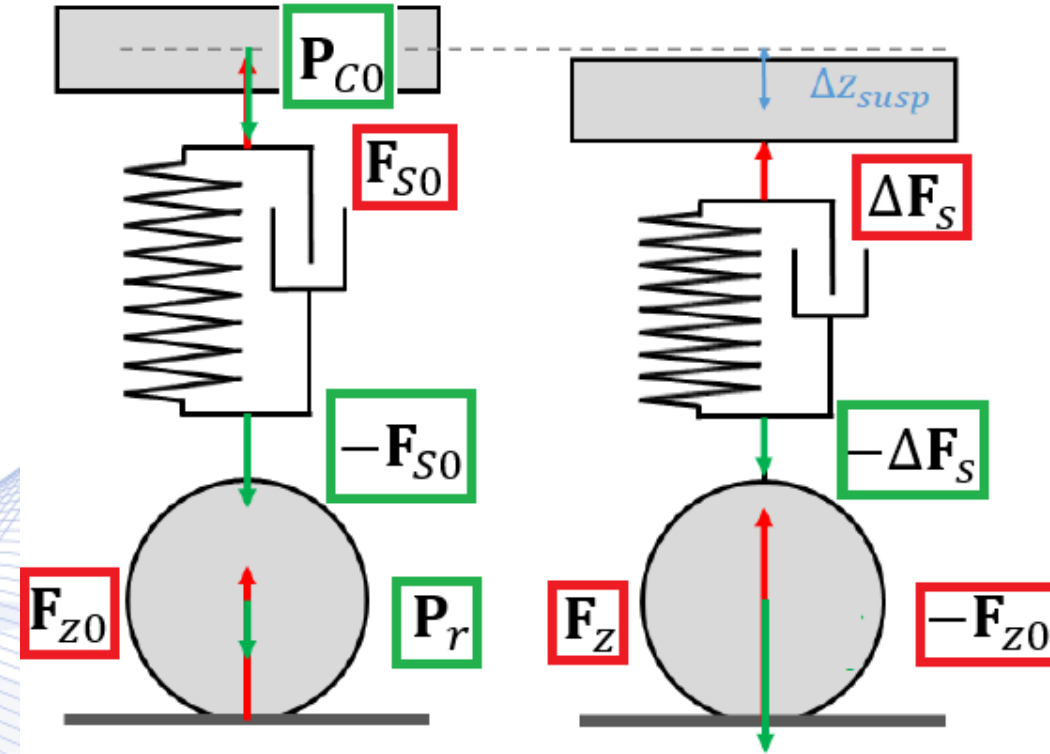

Figure 6: The Wheel Dynamics.

# Tire Dynamics

The **longitudinal**  $F_{xp}$  and **lateral**  $F_{yp}$  forces generated by the road on each tire expressed in the pneumatic frame are obtained from the following four variables:

- The longitudinal slip ratio:  $\tau_x$
- The lateral slip angle:  $\alpha$
- The normal reaction force of the road on the wheel:  $F_z$
- The road friction coefficient:  $\mu$

# Tire Dynamics

Figure 8: The main concept of the tire dynamics.

The ***Tire model*** can be expressed from the following Equations:

$$F_{xp} = f_x(\tau_x, \alpha, F_z, \mu)$$

$$F_{yp} = f_x(\alpha, \tau_x, F_z, \mu)$$

# Tire Dynamics

The first Equation refers to the **Traction** phase while the second Equation refers to the **Braking** phase.

$$\tau_{xi} = \frac{r_{eff}\omega_i - V_{xpi}}{r_{eff}|\omega_i|}, r_{eff}\omega_i \geq V_{xpi}$$

$$\tau_{xi} = \frac{r_{eff}\omega_i - V_{xpi}}{V_{xpi}}, r_{eff}\omega_i \leq V_{xpi}$$

Figure 9: Forces on the Tire Dynamic Model [POL18].

# Tire Dynamics

Now, we must describe the **lateral slip angle**  $a_i$

It is the wheel's orientation vector  $i$  and the velocity vector of the same wheel as shown in Figure 10.

Figure 10: Lateral slip angle on the Tire Dynamic Model [POL18].

# Tire Dynamics

The first Equation refers to the front wheels while the second Equation refers to the rear wheels.

$$\alpha_i = \delta_f - \text{atan}\left(\frac{V_y + l_f \dot{y}}{V_x + \epsilon l_w \dot{y}}\right)$$

$$\alpha_i = -\text{atan}\left(\frac{V_y + l_r \dot{y}}{V_x + \epsilon l_w \dot{y}}\right)$$

Figure 11: The Friction circle.

# Tire Dynamics

10 DoF

Finally, the combination of the principles of the **car – body dynamics** with a **tire model** we get a 10 Degrees of Freedom vehicle model (10 DoF).

Figure 12: The proposed model vehicle model [POL18].

# Kinematic Models

The Equations for this model are simpler. The kinematic vehicle model assumes that no slip occurs between the ground and the wheels, which is accurate for vehicles moving at low speeds.

In this case, the velocity directions at points  $F$  and  $R$  ( $V_F$  and  $V_R$ ) are consistent with the directions of the front and rear wheels

# Kinematic Models

$$\dot{X} = V_G \cos(\psi + \beta)$$

$$\dot{Y} = V_G \sin(\psi + \beta)$$

$$\dot{\psi} = V_G \cos(\beta) \tan(\delta) / (l_f + l_r)$$

$$\dot{V}_G = \alpha$$

$$\beta = \tan^{-1} \left( \frac{l_r}{l_f + l_r} \tan(\delta) \right)$$

Figure 13: Diagram of the four wheel Kinematic model [MWCZ19].

# Bicycle – Car Kinematic Model

Because the bicycle model is often mentioned in the literature, efforts have been made to form the basis for the study and development of corresponding car models.

In the picture below we see how a bicycle model can be adapted to a kinematic vehicle model with four wheels.

# Bicycle – Car Kinematic Model

# Point – Mass Models

As we described in the Introduction the ***Point - Mass*** models are the simplest models of a vehicle.

The latter is assimilated to a point - mass where the ***control inputs*** are good enough for a second order point - mass model. The accelerations in the inertial frame are the  $a_x$  and  $a_y$ .

# Point – Mass Models

The most important is that the system obtained is a linear one.

$$\dot{\xi}_{pm} = \mathbf{A}\xi_{pm} + \mathbf{B}U_{pm}$$

The second order point - mass model can be described from  $p_m = (X, \dot{X}, Y, \dot{Y})^T$  which is the state of the vehicle and  $U_{pm} = (X, Y)^T$  which is the control input. The  $\mathbf{A}$  and  $\mathbf{B}$  are diagonal  $4 \times 4$  and  $2 \times 2$  matrices, respectively. The variables  $X$  and  $Y$  describe the **positions** of the vehicle in the inertial frame while the  $\dot{X}$  and  $\dot{Y}$  describe the **speed** of the vehicle in the inertial frame.

# Point – Mass Models

As shown in Figure 15 the vehicle can move in many directions, this idea makes the model **weak** and **poor** in accuracy. If we want to avoid pure lateral motion, we assume the following Equation.

$$|\dot{Y}| \leq k|\dot{X}|$$

where,

$$0 < \tan(\psi_{max}) < 1$$

Figure 15: The proposed Point - Mass model [POL18].

# Autonomous Vehicle Control

In order to execute the reference path or trajectory from the motion planning system a ***feedback controller*** is used to select appropriate actuator inputs to carry out the planned motion and correct tracking errors.

The tracking errors generated during the execution of a planned motion are due in part to the inaccuracies of the vehicle model.

# Model Predictive Control Law

The ***Model Predictive Control*** (MPC) model consist of a general and common methodology for autonomous vehicles control. The MPC method solves the motion planning problem over a short time horizon, by taking a short interval of the resulting open loop control and apply it to the system.

The model takes the form of a general continuous time control system with control,  $u(t) \in \mathbb{R}^m$  and the state,  $x(t) \in \mathbb{R}^n$ .

# Pure Pursuit Control Law

The pure pursuit is a lateral control strategy. In this control law, a goal point is defined on the desired path, by looking ahead distance  $l_d$  from the current position of the rear axle center  $O$  to the desired path.

Then the curvature of the arc that connects  $O$  to the goal point is calculated geometrically.

# Stanley Control Law

This Law was first introduced in Stanford University and won the DARPA Grand Challenge.

$$\phi(t) = \theta_p(t) + \tan^{-1}\left(\frac{d_f(t)}{l_d}\right)$$

Figure 17: The Stanley Control Law [DAGM16].

# Modified Sliding Control Law

The sliding mode is a robust control model and does not require a precise model of the system and can also ensure stability. The sliding surface can be defined as following:

$$\psi = k_{\theta p} \theta_p + k_d d_r$$

where the  $k_p$  and  $k_d$  are weighting coefficients. The sliding mode controller assumes that:

$$\dot{\psi} = -K_{\psi} \text{sign}(\psi)$$

- Deep Autonomous Vehicle Control

# Kinematic Lateral Speed Control Law

The new ***kinematic*** lateral speed control designed to control the rear lateral distance and the orientation error by controlling the lateral speed  $d_r$ , which in turn is controlled by the angular speed of the car  $\dot{\theta}$  through the steering angle  $\phi$ .

As the lateral speed  $d_r$  is under control, the motions toward the path are smoother, after tuning the parameters.

# Kinematic Lateral Speed Control Law

If the car is far away from the road line, it must get closer at higher speed than if it is near, so the desired lateral speed  $\hat{d}_r$  can be defined as proportional to the lateral error  $d_r$ , with negative sign.

$$\hat{d}_r = -k_{lat}d_r$$

The absolute value of the desired lateral speed is limited to a reasonable maximum value, which in our case is 1 m/s.

# Kinematic Lateral Speed Control Law

The derivative of the lateral speed of the rear axle  $d_r$  is defined from the following Equation:

$$\dot{d}_r = v_u \sin(\theta_p)$$

Figure 18: The Kinematic Lateral Control Law [DAGM16].

# Deep Autonomous Vehicle Control

**Deep Learning** models contribute to perception and to the processing of the sensory data in order to make informed decisions. The popular deep learning models used in autonomous car technology include:

- End – to end Learning
  - Fully Convolutional Network
  - Deep Reinforcement Learning
- CNN and Deep CNN  
Deep Boltzmann Machines  
Deep Autoencoders

# Deep Autonomous Vehicle Control
